

Flexible and Dynamic Device Management Solution

DEVICE PROVISIONING

Device Provisioning is a one stop solution for Device Security, User Management, Access Management, and Data Security & Privacy.

FEATURES & BENEFITS

Device Management

Device provisioning application provides a central location for managing devices connected with each user profile. Before using an organizational application, the users will have to register the mobile device with the portal using the mobile application. This will ensure a central depository of mobile devices authenticated against a valid user profile. Users will only be able to use organizational applications on registered mobile devices. This provides a one stop solution for granting and revoking device access in cases such as device misplacement, theft and reselling.

User Management and Universal Credentials

Device provisioning portal will maintain a list of registered users, their cross application login credentials and application access list. Device Provisioning solution can therefore act as a one stop solution for granting and revoking access for any organizational user with one single action in case of events such as employee resignation, change in employee access rights etc.

Access Management

The portal also maintains a list of applications that each organizational user has access too. Only those applications will be available for download to the user through the device provisioning mobile application. Rights of any user pertaining to each organizational application can also be altered using the portal interface, providing a single solution for granting or revoking access.

Privacy & Data Security

Organizational Applications deal with sensitive data that cannot be shared with unauthorized users. Device provisioning solution provides a two layer security for each application by managing a list of each user's login credentials and also the list of authenticated devices that can be used for accessing these applications.

Enterprise Architecture

Device provisioning features an enterprise architecture which provides organizations with open hooks for adding any application under the purview of device provisioning security layer.
